When asthmatics are awake, they will or can turn to their inhalers to open their airways. But when they sleep, many of them continue to struggle with breathing and are helpless - their sleep-related problems may help doctors better diagnose and treat their patients’ asthma.

Repeated arousals during sleep are common in obstructive sleep apnea and in nocturnal asthma. This may also result in changes in oronasal airflow, decreases of saturation and respiratory effort changes. Frequently nocturnal asthmatics may mimic symptoms of OSA with daytime sleepiness (1-4).

A significant number of nocturnal asthmatics may have OSA also. This may be due to high incidence of both in the general population. Gastro-esophageal reflux disease (GERD) may also result in these people with may produce upper and lower airway inflammation (5). The negative airway pressure increases during apneic episodes to overcome upper airway obstruction may produce gastric reflux (6).

Nasopharyngeal congestion may predispose to worsening of bronchoconstriction and OSA as a result of mouth breathing. Irritation of the upper airways produce periodic breathing and decreased upper airway obstruction during sleep in nocturnal asthmatics. Increased bronchial activity may be due to hypoxemia in these cases. Recurrent episodes of coughing, choking and breathlessness are common in both.

Treatment with methyl xanthines, beta agonists and systemic steroids lead to fragmented sleep like in OSA in nocturnal asthmatics (7).

Nocturnal asthma and OSA have similar circadian patterns with changes in peak expiratory flow rates and forced expiratory volume in one second (FEV1) in early morning hours (8,9). Exhaled nitric oxide is lower in the morning in asthmatics leading to more bronchoconstriction and increase in airway resistance (10,11). Melatonin is high in asthmatics during night which may also increase symptoms at night due to proinflammatory effects (12).

Number of eosinophils (13,14) and levels of cortisol (15,16) may contribute to airway inflammation in asthma during night. Because of these reasons, nocturnal asthma may be considered as some other form of sleep disordered breathing (SDB).

SDB symptoms like insomnia, excessive day time somnolence are common in asthma (17,3-5). 55% of the asthmatics reported excessive somnolence and 47% had a score of more than 11 on the Epworth Sleepiness Scale (18,19). 49% men and 33% women met criteria for OSA by the Sleep Apnea Scale of Sleep Disorders Questionnaire (SA-SDQ) (21) thus concluding beyond doubt that symptoms of SDB are common in asthmatics. High prevalence of snoring and correlation to SA-SDQ is common in asthmatics (21).

Continuous positive airway pressure therapy (CPAP) may be useful in the treatment of nocturnal asthma in apneic asthmatics (22,23). The CPAP improves nocturnal and diurnal peak expiratory flow up to two weeks after beginning of therapy in those with OSA and nocturnal asthma (24). In those with nocturnal asthma alone, the expiratory flow worsened and sleep quality was disrupted. The use of oxygen alone has been found to be useful in nocturnal asthma.

The above data illustrates the importance of polysomnographic studies in nocturnal asthmatics who have OSA.

Do all nocturnal asthmatics need a polysomnographic evaluation?
